Lab: Dictionaries

Problems for in-class lab for the Python Fundamentals Course @SoftUni. Submit your solutions in the SoftUni judge system at https://judge.softuni.org/Contests/1736.

1. Bakery

Your first task at your new job is to create a table of the stock in a bakery, and you really don't want to fail on your first day at work.

You will receive a single line containing some food (keys) and quantities (values). They will be separated by a single space (the first element is the key, the second – the value, and so on). Create a dictionary with all the keys and values and **print** it on the console.

Example

Input	Output
bread 10 butter 4 sugar 9 jam 12	{'bread': 10, 'butter': 4, 'sugar': 9, 'jam': 12}
eggs 3 sugar 7 salt 1 butter 3	{'eggs': 3, 'sugar': 7, 'salt': 1, 'butter': 3}

Hint

Let us start with reading the input and creating an empty dictionary:

```
6 01-bakery.py
     elements = input().split(" ")
     bakery = {} # bakery = dict()
```

Note that there are 2 ways of creating a dictionary (with the curly braces or using the dict() method).

Since we know that we will get key-value pairs, we can use a for-loop with step 2. We take the key and the value and **add** them to the dictionary, and after the **loop** is **over**, we **print** it:

```
for i in range(0, len(elements), 2):
4
          kev = elements[i]
          value = elements[i + 1]
6
         bakery[key] = int(value)
     print (bakery)
```

Note that the value must be an integer (since it is a quantity).

2. Stock

After you have completed your first task, your boss decides to give you another one right away. Now not only you have to keep track of the stock, but also you should answer customers if you have some products in stock or not.

You will be given key-value pairs of products and quantities (on a single line separated by space). On the following line, you will be given products to search for. Check for each product. You have 2 possibilities:

- If you have the product, print "We have {quantity} of {product} left".
- Otherwise, print "Sorry, we don't have {product}".

Example

Input	Output
cheese 10 bread 5 ham 10 chocolate 3 jam cheese ham tomatoes	Sorry, we don't have jam We have 10 of cheese left We have 10 of ham left Sorry, we don't have tomatoes
eggs 5 bread 10 bread eggs	We have 10 of bread left We have 5 of eggs left

Hint

We repeat the steps from the previous task for reading the products and adding them to the dictionary.

```
1
     elements = input().split(" ")
     bakery = \{\}
     for i in range(0, len(elements), 2):
4
          key = elements[i]
         value = elements[i + 1]
6
         bakery[key] = int(value)
```

Next, we read the products we have to search for and check for each of them.

```
searched products = input().split(" ")
9
      for product in searched products:
          if product in bakery:
              print(f"We have {bakery[product]} of {product} left")
11
          else:
              print(f"Sorry, we don't have {product}")
```

3. Statistics

You seem to be doing great at your first job, so your boss decides to give you as your next task something more challenging. You have to accept all the new products coming in the bakery and finally gather some statistics.

You will be receiving key-value pairs on separate lines separated by ": " until you receive the command "statistics". Sometimes you may receive a product more than once. In that case, you have to add the new quantity to the existing one. When you receive the "statistics" command, print the following:

```
"Products in stock:
```

```
- {product1}: {quantity1}
- {product2}: {quantity2}
```

- {productN}: {quantityN}

Total Products: {count_all_products} Total Quantity: {sum_all_quantities}"

Example

Input Output

```
bread: 4
                      Products in stock:
cheese: 2
                      - bread: 5
ham: 1
                      - cheese: 2
bread: 1
                      - ham: 1
                      Total Products: 3
statistics
                      Total Quantity: 8
                      Products in stock:
eggs: 10
bread: 6
                      - eggs: 10
cheese: 8
                      - bread: 6
milk: 7
                      - cheese: 8
statistics
                      - milk: 7
                      Total Products: 4
                      Total Quantity: 31
```

Hint

Let us start by creating the dictionary and creating a while loop

```
1
     products = {}
2
3
     command = input()
4
     while command != "statistics":
5
          command = input()
```

Now, let us get the product and the quantity

```
while command != "statistics":
4
5
          tokens = command.split(": ")
          product = tokens[0]
6
7
          quantity = int(tokens[1])
```

Then, we want to create a check if the product is not already in the dictionary and set its value to 0

```
while command != "statistics":
4
         tokens = command.split(": ")
         product = tokens[0]
6
7
         quantity = int(tokens[1])
         if product not in products:
9
             products[product] = 0
```

That way, we make sure that the **product will exist** before we add the **quantity**

Then we add up the quantity

```
if product not in products:
9
             products[product] = 0
         products[product] += quantity
```

And finally, we print the result

```
13
      print("Products in stock:")
14
      for (product, quantity) in products.items():
          print(f"- {product}: {quantity}")
      print(f"Total Products: {len(products.keys())}")
16
17
      print(f"Total Quantity: {sum(products.values())}")
```

- For the total products, we get the length of the keys
- For the total quantity, we sum the values

```
[print(f"- {product}: {quantity}") for (product, quantity) in products]
```

4. Students

You will be receiving names of students, their ID, and a course of programming they have taken in the format "{name}:{ID}:{course}". On the last line, you will receive a name of a course in snake case lowercase letters. You should print only the information of the students who have taken the corresponding course in the format: "{name} - {ID}" on separate lines.

Note: each student's ID will always be unique

Input	Output
Peter:123:programming basics John:5622:fundamentals Maya:89:fundamentals Lilly:633:fundamentals fundamentals	John - 5622 Maya - 89 Lilly - 633
Alex:6:programming basics Maria:7:programming basics Kaloyan:9:advanced Todor:10:fundamentals programming_basics	Alex - 6 Maria - 7

5. ASCII Values

Write a program that receives a list of characters separated by ", ". It should create a dictionary with each character as a key and its ASCII value as a value. Try solving that problem using comprehension.

Examples

Input	Output
a, b, c, a	{'a': 97, 'b': 98, 'c': 99}
d, c, m, h	{'d': 100, 'c': 99, 'm': 109, 'h': 104}

6. Odd Occurrences

Write a program that prints all elements from a given sequence of words that occur an odd number of times (caseinsensitive) in it.

- Words are given on a **single line**, space-separated.
- Print the result elements in **lowercase**, in **their order of appearance**.

^{*}Another way of implementing lines 14 and 15 would be by using dictionary comprehension

Examples

Input	Output
Java C# PHP PHP JAVA C java	java c# c
3 5 5 hi pi HO Hi 5 ho 3 hi pi	5 hi
aaA SQL xx axx aA a XX c	a sql xx c

Hints

Read a line from the console and **split it by a space**, and create a **dictionary**:

```
6 04-odd-occurrences.py
        words = input().split(" ")
1
2
        dictionary = {}
```

Create a loop and check for each word (lower case) if it is in the dictionary, and if it is not, add it:

```
for word in words:
4
         word lower = word.lower()
         if word lower not in dictionary:
6
              dictionary[word lower] = 0
         dictionary[word lower] += 1
```

Then create another loop using the items() method and check if the number of occurrences of the current word is odd. If it is, print it:

```
for (key, value) in dictionary.items():
9
         if value % 2 != 0:
             print(key, end=" ")
```

7. Word Synonyms

Write a program, which keeps a dictionary with synonyms. The key of the dictionary will be the word. The value will be a list of all the synonyms of that word. You will be given a number n – the count of the words. After each term, you will be given a synonym, so the count of lines you should read from the console is 2 * n. You will be receiving a word and a synonym each on a separate line like this:

- {word}
- {synonym}

If you get the same word twice, just add the new synonym to the list.

Print the words in the following format:

```
{word} - {synonym1, synonym2 ... synonymN}
```

Examples

Input	Output	
3 cute adorable cute charming	cute - adorable, smart - clever	charming

smart clever	
2 task problem task assignment	task – problem, assignment

Hint

We start by reading the number **n** and creating the **dictionary with synonyms**:

```
💪 05-word-synonyms.py 🗵
 1
         n = int(input())
 2
         synonyms = \{\}
```

Then we create a **for loop** to read the **word-synonym pairs**:

```
3
      for i in range(n):
4
          word = input()
5
          synonym = input()
```

We check if the word is not in the dictionary, and in that case, we set its value to an empty list (since one word can have multiple synonyms), and we append the new synonym to that list:

```
6
          if word not in synonyms:
7
              synonyms[word] = []
          synonyms[word].append(synonym)
```

Finally, we **print** the result:

```
for word in synonyms:
9
          print(f"{word} - {', '.join(synonyms[word])}")
10
```
